

MANAGEMENT REPORT

Factors Influencing Customer Satisfaction with Mobile Banking Applications

Among Working Adults in Lagos, Nigeria

1. Executive Summary

This report presents the findings of a primary research study examining the factors that influence customer satisfaction with mobile banking applications among working adults in Lagos, Nigeria. A structured survey was administered to 35 respondents between May 6 and May 10, 2026, capturing five key dimensions of the mobile banking experience: app usability, transaction reliability, security perception, customer support responsiveness, and transaction frequency. All data were analysed in RStudio using descriptive statistics, correlation analysis, and ggplot2 visualisations. The study finds that app usability ($r = 0.521$), customer support ($r = 0.510$), and transaction reliability ($r = 0.484$) are the three strongest predictors of overall satisfaction, while security perception shows a negligible correlation due to low variance in responses. Kuda leads the sample with a mean satisfaction score of 4.09, while Access Bank records the lowest at 3.14, a gap of nearly one full scale point. These findings point to three actionable priorities for mobile banking providers: investing in UI/UX simplification, reducing failed transaction rates, and improving customer support response times. Providers that address these three dimensions systematically are most likely to close the satisfaction gap against market leaders.

2. Research Question and Methodology

Research Question: What factors influence customer satisfaction with mobile banking applications among working adults in Lagos, Nigeria?

This study was motivated by the observable disconnect between the rapid growth of mobile banking adoption in Nigeria and the persistent quality complaints reported by users across social media and customer feedback channels. Understanding which specific service dimensions drive satisfaction rather than aggregate app ratings, is actionable information for product managers, UX teams, and service operations leaders.

A structured survey questionnaire was designed with 13 items across three sections. Section A captured demographic information (age group, gender, primary banking app). Section B measured five

constructs using 5-point Likert scales: app usability (2 items), transaction reliability (2 items), security perception (2 items), customer support responsiveness (2 items), and transaction frequency (1 numeric item). Section C captured overall satisfaction with a single Likert item.

The instrument was distributed via WhatsApp using a Google Form link over a five-day period. Convenience sampling was used, targeting digitally active working adults in Lagos. A total of 35 complete responses were collected. Data were imported into RStudio, cleaned through a systematic workflow (missing value removal, duplicate detection, variable type correction, outlier treatment), and analysed using the tidyverse, psych, and corplot libraries.

3. Key Findings

3.1 Sample Profile

The sample of 35 working adults was predominantly from the 26–35 age bracket (48.6%), with male respondents accounting for 60%. Kuda (31.4%) and Opay (28.6%) were the most commonly used primary banking apps, together representing 60% of the sample. The mean overall satisfaction score was 3.69 out of 5 (SD = 0.53), indicating a moderate but uneven level of satisfaction across the sample.

3.2 Finding 1 — Usability Is the Strongest Driver of Satisfaction

App usability recorded the highest mean score among all constructs (Mean = 3.97, SD = 0.61) and the strongest Pearson correlation with overall satisfaction ($r = 0.521$). Respondents who found their apps easy to navigate and transact on were significantly more likely to report high satisfaction. The scatter plot below confirms the positive linear trend, with Kuda and Opay users clustering toward the upper right.

Figure 1: App Usability vs. Overall Satisfaction ($r = 0.521$) — Source: RStudio EDA

Banks with below-average usability scores, particularly Access Bank (Mean Usability = 3.43) stand to gain the most from UX investment. Simplifying transaction flows and reducing the number of screens required to complete a transfer are the highest-return improvements available to these providers.

3.3 Finding 2 — Transaction Reliability Drives Dissatisfaction

Transaction reliability scored the lowest mean of all four service quality constructs (Mean = 3.47, SD = 0.65) and the widest spread, indicating it is both the weakest and most variable dimension of the mobile banking experience. Its correlation with satisfaction ($r = 0.484$) confirms that failed or reversed transactions are a direct driver of user dissatisfaction. The boxplot below shows that reliability has the widest interquartile range of any construct, meaning opinions on this dimension are more polarised than on usability or security.

Figure 2: Boxplot of Construct Scores — Reliability Has Widest Spread — Source: RStudio EDA,

The low reliability mean is particularly damaging for Access Bank (Mean Reliability = 3.14) and Other apps (Mean = 2.67). Banks in this position face a compounding problem — users who encounter frequent failed transactions not only leave with lower satisfaction but are also less likely to increase their transaction frequency, further limiting revenue potential.

3.4 Finding 3 — Kuda Leads; Access Bank Trails the Market

The management chart below presents mean satisfaction scores by app, ranked from highest to lowest. Kuda leads with 4.09, followed by GTBank at 4.00, both above the overall sample mean of 3.69. Opay sits marginally below the mean at 3.60 despite being the second most widely used app. Access Bank records the lowest score at 3.14, representing a 0.95-point gap from the market leader.

Figure 3: Average Satisfaction by App — Management Report Chart — Source: RStudio EDA

App	Mean Satisfaction	Mean Usability	Mean Reliability	Mean Support	N
Kuda	4.09	4.32	4.05	3.95	11
GTBank	4.00	3.62	3.38	3.00	4
Opay	3.60	4.20	3.35	3.05	10
Other	3.33	3.67	2.67	2.83	3
Access Bank	3.14	3.43	3.14	2.79	7

Table 1: App-Level Performance Summary | All scores on a 1–5 scale

Business implication: The 0.95-point satisfaction gap between Kuda and Access Bank is not a coincidence it mirrors consistent score differences on usability, reliability, and support. This table gives underperforming banks a clear benchmark and identifies which dimensions require the most urgent improvement.

4. Business Recommendations

The following three recommendations are derived directly from the survey data and EDA findings. Each recommendation identifies the responsible function, the evidence base, and a measurable success criterion.

R1	Prioritise UI/UX Investment for Underperforming Apps Banks scoring below 3.6 on usability (Access Bank: 3.43, Others: 3.67) should conduct user journey audits focused on the transaction completion flow. Specifically: reduce the number of screens required to transfer funds, introduce biometric shortcuts, and conduct moderated usability testing with existing customers. Target metric: Usability composite score above 4.0 within two product release cycles.
R2	Reduce Failed and Reversed Transaction Rates Through Infrastructure Investment Transaction reliability is the weakest construct in the dataset (Mean = 3.47) and the second strongest predictor of satisfaction ($r = 0.484$). Banks with reliability scores below 3.5 should investigate and resolve root causes of failed transactions, including switch downtime, network timeout thresholds, and core banking integration failures. A public-facing transaction success rate dashboard would also improve user trust. Target metric: Transaction reliability composite score above 3.8 within six months.
R3	Establish Customer Support Response-Time SLAs and Track Them as a KPI Customer support records the lowest mean of all constructs (3.26) and the second highest correlation with satisfaction ($r = 0.510$). Banks should implement and enforce Service Level Agreements (SLAs) for complaint resolution, for example, a maximum 4-hour first response time for in-app complaints and a 48-hour resolution target for disputed transactions. Support performance should be reported monthly to senior leadership alongside satisfaction scores. Target metric: Support composite score above 3.75 within 12 months.

5. AI Augmentation Summary

ChatGPT (GPT-4o) was used at three distinct points during this analytical project: to generate and improve R code for data cleaning, to recommend an appropriate EDA chart set, and to interpret the correlation matrix for a non-technical audience.

Where AI added value: The code generation assistance reduced the time required to write the data cleaning script. The AI correctly identified the `lapply()` and `rowMeans()` patterns needed for batch operations and produced code that was syntactically correct on the first attempt. Its chart selection advice was analytically sound and helped confirm that the planned EDA structure met both statistical and management communication standards.

Where AI fell short: The most significant error occurred during result interpretation, when the AI characterised the low Security correlation as evidence that security was irrelevant to customer satisfaction. This is statistically incorrect, the low correlation reflects restricted range in the Security variable (most respondents scored it between 3.5 and 4.5), not absence of importance. Left uncorrected, this misinterpretation would have produced a misleading management recommendation. The AI also made structural assumptions about the dataset column order that required manual correction.

Overall assessment: AI tools are most valuable for time-consuming but rule-governed tasks such as code drafting and formatting. They are least reliable when statistical nuance is required specifically when distinguishing between 'no correlation' and 'no variance.' Human judgment, domain knowledge, and line-by-line verification of AI outputs remain essential for producing credible analytical work.
